***Abstract*—Emergency response systems globally face the critical "Golden Hour" challenge, where delayed medical intervention directly correlates with increased mortality rates. In India alone, road accidents claimed over 1.73 lakh lives in 2023, with studies indicating that 30-40% of these deaths could have been prevented with timely first-response care. While crowdsourcing platforms offer a promising paradigm for mobilizing citizen volunteers, the effective assignment of these volunteers remains computationally complex due to three fundamental challenges: (1) the *heterogeneity of resources*—volunteers possess varying skills (CPR certification, trauma care), biological attributes (blood types), and physical assets (vehicles, first-aid kits); (2) the *prevalence of system noise*—false alarms and prank calls waste critical volunteer man-hours; and (3) the *absence of severity-aware prioritization*—existing systems treat a minor injury identically to a life-threatening cardiac arrest.**

This paper proposes a Priority-Aware Dynamic Allocation Framework integrated into the "LifeSaverLink" emergency response ecosystem. We introduce a novel mathematical model featuring: (a) a multi-attribute volunteer profiling system capturing biological, skill-based, and asset-based attributes; (b) a probabilistic noise filter based on call correctness probability (ρ); (c) a severity-indexed prioritization mechanism (σ); and (d) multi-attribute compatibility constraints for biological matching (blood donation compatibility) and collective asset coverage. We formalize the problem as a Dynamic Spatio-Temporal Multi-Objective Optimization Problem (DST-MOOP) and prove its NP-Hardness via reduction from the Dual Bin Packing Problem.

We propose the Resource-Aware NBFA (Iterative Best Fit Algorithm), a three-phase heuristic incorporating noise filtering, eligibility pruning, and utility-based assignment. Extensive simulations on a synthetic urban grid (20$\times$20 km, 100 volunteers, 200 emergency requests) demonstrate: (i) 28% reduction in response latency for high-severity cases; (ii) 85% reduction in wasted volunteer man-hours through false alarm filtering; (iii) 100% biological compatibility compliance; and (iv) 40% improvement in long-term volunteer retention through fatigue-aware scheduling. A comprehensive case study of a multi-vehicle highway accident illustrates the practical application of the framework.

***Index Terms*—Crowdsourced Emergency Response, Volunteer Mobilization, Multi-Objective Optimization, Blood Compatibility Matching, Dynamic Team Formation, Severity-Aware Dispatch, NP-Hard Problems, Golden Hour, Resource Heterogeneity**

I. Introduction

THE efficacy of emergency medical response hinges critically on the temporal dimension—every minute of delay in trauma care correlates with measurably reduced survival probabilities. The medical community has long recognized the "Golden Hour" principle, which posits that trauma patients receiving definitive care within 60 minutes of injury have significantly improved outcomes [2]. Yet, in developing nations with constrained healthcare infrastructure, this golden window is routinely missed.

A. The Indian Emergency Response Crisis

India presents a particularly acute case study in emergency response challenges. According to the Ministry of Road Transport and Highways [1], road accidents in 2023 resulted in:

- **4,61,312** total road accidents reported
- **1,73,558** fatalities (one death every 3 minutes)
- **4,43,366** persons injured
- Average emergency response time: **25-45 minutes** in urban areas, **60+ minutes** in rural areas

Medical studies estimate that **30-40% of road accident deaths** occur due to delayed pre-hospital care—victims who could have survived with basic first aid, hemorrhage control, or CPR within the first 10-15 minutes [3]. The existing Emergency Response Support System (ERSS-112), while providing a unified emergency number, suffers from centralized dispatch bottlenecks, limited ambulance availability, and an inability to leverage trained citizens who may be located much closer to the incident.

B. The Promise and Challenge of Crowdsourced Response

Crowdsourcing has emerged as a transformative paradigm for emergency response. Applications like *PulsePoint* in the United States have demonstrated that alerting nearby CPR-trained citizens to cardiac arrest events can significantly improve survival rates [6]. The fundamental insight is compelling: in dense urban environments, a trained volunteer is often within 2-3 minutes of any location, while the nearest ambulance may be 15-20 minutes away.

However, scaling crowdsourced emergency response beyond single-skill scenarios (e.g., CPR-only) introduces substantial algorithmic complexity. Consider a realistic highway accident scenario:

Example 1 (Multi-Resource Emergency)**.** *A multi-vehicle collision on NH-44 near Hyderabad involves three victims:*

1) ***Victim A**: Severe hemorrhage, requires O-negative blood transfusion, trauma care, and vehicle extraction*
2) ***Victim B**: Cardiac arrest, requires immediate CPR*
3) ***Victim C**: Minor fractures, requires first aid and transport to hospital*

The emergency dispatch system must simultaneously find volunteers who: possess CPR certification; have compatible blood types; own vehicles capable of patient transport; are not already fatigued from recent dispatches; and are located within feasible response distances.

This example illustrates why treating volunteers as "generic nodes" (as in ride-sharing algorithms) fundamentally fails for emergency response. The volunteer assignment problem becomes a complex multi-attribute matching problem with heterogeneous resources, hard biological constraints, and severity-differentiated objectives.

C. Research Gaps and Contributions

Existing approaches in crowdsourced task assignment [4] focus primarily on minimizing travel cost or maximizing task completion rates. They fail to address:

1) **Resource Heterogeneity**: Volunteers possess diverse attributes—skills (CPR, trauma care), biological properties (blood type), and physical assets (vehicles, equipment). Matching must consider all dimensions.
2) **Biological Compatibility Constraints**: Blood donation and transfusion require strict ABO-Rh compatibility. Dispatching an incompatible donor is not merely suboptimal—it is medically dangerous.
3) **Noise and False Alarms**: Crowdsourced systems are susceptible to prank calls, accidental triggers, and misreported emergencies. Dispatching volunteers to false alarms wastes critical resources and causes volunteer fatigue.
4) **Severity-Aware Prioritization**: A cardiac arrest (survival window: 4-6 minutes) requires fundamentally different response urgency than a minor fracture. Existing algorithms treat all requests uniformly.
5) **Volunteer Sustainability**: Over-dispatching "nearest" volunteers leads to burnout and platform abandonment. Long-term system viability requires fatigue-aware load balancing.

This paper makes the following contributions:

1) **Heterogeneous Volunteer Profiling Model**: We formalize a composite attribute vector $v_j = \langle B_j, S_j, A_j, F_j, P^j_{acc} \rangle$ capturing biological, skill-based, asset-based, fatigue, and acceptance probability dimensions.
2) **Noise-Resilient Prioritization**: We introduce correctness probability (ρ_i) for filtering false alarms and severity index (σ_i) for urgency-based prioritization.
3) **Weighted Utility Maximization Model**: We formulate an objective function that maximizes survival utility (not merely minimizes distance), incorporating severity, correctness, compatibility, and fatigue factors.
4) **Resource-Aware NBFA Algorithm**: We propose a three-phase heuristic—noise filtering, eligibility pruning, utility-based assignment—that achieves near-optimal solutions in polynomial time.
5) **Comprehensive Simulation and Case Study**: We validate the framework through extensive simulations and a detailed walkthrough of a realistic multi-victim accident scenario.

D. Paper Organization

The remainder of this paper is organized as follows: Section II reviews related work in emergency response systems, crowdsourcing algorithms, and blood donation platforms. Section III presents the system architecture of the LifeSaverLink framework. Section IV develops the mathematical model, formalizes the optimization problem, and proves NP-Hardness. Section V describes the Resource-Aware NBFA algorithm. Section VI presents simulation results with detailed graph analysis. Section VII provides a comprehensive case study with step-by-step problem solving. Section VIII discusses limitations and ethical considerations. Section IX concludes with future research directions.

II. Related Work

The proposed framework draws from and extends research in three interconnected domains: emergency response platforms, crowdsourcing algorithms, and blood donation management systems.

A. Emergency Response Platforms

1) Global Initiatives: The *PulsePoint* application, deployed across 4,000+ communities in the United States, represents the most successful implementation of crowdsourced cardiac arrest response [6]. When a 911 call reports a cardiac arrest, PulsePoint simultaneously alerts CPR-trained citizens within a 400-meter radius. Studies have shown that bystander CPR rates increased by 12-15% in PulsePoint-enabled areas.

However, PulsePoint's design is inherently limited:

- **Single-skill focus**: Only addresses cardiac arrest; cannot handle multi-skill emergencies
- **No resource matching**: Does not consider volunteer assets (vehicles, equipment)
- **No biological constraints**: Irrelevant for CPR but critical for trauma with blood loss
- **Uniform alerting**: All nearby volunteers receive alerts regardless of fatigue or availability

2) Indian Initiatives: India's Emergency Response Support System (ERSS-112) provides a unified emergency number but relies entirely on centralized dispatch of government ambulances [5]. The system lacks:

- Citizen volunteer mobilization capability
- Real-time tracking of trained responders
- Integration with blood bank inventories
- Severity-based triage logic

The *GVK EMRI 108* ambulance network operates in 15 states but faces chronic resource constraints—average response times exceed 20 minutes in most urban areas and 45+ minutes in rural regions.

TABLE I: Gap Analysis: Existing Systems vs. LifeSaverLink

Feature	Pulse-Point	ERSS-112	e-Rakt-Kosh	LSL
Multi-skill matching	55	55	55	51
Blood compatibility	55	55	Partial	51
Severity prioritization	55	55	55	51
False alarm filter	55	55	N/A	51
Fatigue management	55	55	55	51
Asset tracking	55	Partial	55	51
Real-time dispatch	51	51	55	51

B. Crowdsourcing Task Assignment Algorithms

1) Classical Approaches: The crowdsourcing literature has extensively studied worker-task assignment problems. We formalized the "Concurrent Team Formation" problem, proving that forming teams with complementary skills to meet task thresholds is NP-Hard. Their work introduced the Minimum Reward Problem (MRP), which minimizes payment cost while ensuring skill coverage.

However, MRP and related formulations assume:

- Workers are interchangeable within skill categories
- Tasks are delay-tolerant (no urgency differentiation)
- Cost minimization is the primary objective
- No biological or hard compatibility constraints exist

2) Spatial Crowdsourcing: Kazemi and Shahabi [8] introduced spatial crowdsourcing, where tasks and workers have geographic locations. Their Maximum Task Assignment (MTA) problem maximizes completed tasks subject to travel distance constraints. Subsequent work incorporated time windows, worker preferences, and dynamic arrivals.

These formulations remain inadequate for emergency response because:

- They optimize for task *completion count*, not *survival probability*
- Urgency is modeled as binary (deadline met/missed), not continuous
- No mechanism exists for filtering unreliable task reports

C. Blood Donation and Matching Systems

India's *e-RaktKosh* portal digitizes blood bank inventory management but operates as a passive registry [7]. Users can search for blood availability but cannot:

- Request real-time donor mobilization
- Verify donor eligibility (last donation date, hemoglobin levels)
- Integrate with emergency dispatch systems

Volunteer blood donation apps like *BloodConnect* and *Simply Blood* maintain donor registries but lack:

- Location-based real-time matching
- Compatibility verification logic
- Integration with broader emergency response workflows

D. Research Gap Summary

Table I summarizes the capabilities of existing systems versus the requirements addressed by our framework.

III. Mathematical Modeling and Problem Formulation

We model the emergency response environment as a dynamic bipartite graph where Emergency Requests (E) and Volunteers (V) interact under strict spatiotemporal constraints. This section formalizes the problem mathematically and proves its computational complexity.

A. Notation Summary

Table II provides a comprehensive summary of all mathematical notation used in the paper.

TABLE II: Mathematical Notation

Symbol	Description
Sets	
E	Set of emergency requests $\{r_1, r_2, \ldots, r_m\}$
V	Set of volunteers $\{v_1, v_2, \ldots, v_n\}$
$\mathcal{B}$	Set of blood types $\{O^-, O^+, A^-, A^+, B^-, B^+, AB^-, AB^+\}$
$\mathcal{S}$	Set of skills $\{CPR, FirstAid, Trauma, \ldots\}$
$\mathcal{A}$	Set of assets $\{Car, SUV, FirstAidKit, \ldots\}$
Request Parameters	
σ_i	Severity index of request r_i ($1 \leq \sigma \leq 10$)
ρ_i	Correctness probability of request r_i ($0 \leq \rho \leq 1$)
L_i	Geographic location (latitude, longitude) of r_i
$Req_B(r_i)$	Blood type requirement (if any)
$Req_S(r_i)$	Required skill set
$Req_A(r_i)$	Required asset set
P_i	Priority score $= \sigma_i \times \rho_i$
Volunteer Attributes	
B_j	Blood type of volunteer v_j
S_j	Skill set of volunteer v_j
A_j	Asset set of volunteer v_j
F_j	Fatigue score ($0 \leq F \leq 1$)
P^j_{acc}	Historical acceptance probability
L_j	Current location of v_j
Derived Quantities	
d_{ij}	Euclidean distance between L_i and L_j
T_{ij}	Estimated travel time from v_j to r_i
$M_B(d, r)$	Blood compatibility matrix entry
$I_{compat}(i, j)$	Compatibility indicator function
U_{ij}	Utility of assigning v_j to r_i
Decision Variables	
x_{ij}	Binary: 1 if v_j assigned to r_i, 0 otherwise
Parameters	
δ	Noise filter threshold (default: 0.3)
θ	Fatigue threshold (default: 0.8)
R_{base}	Base search radius (km)
η	Severity-radius scaling factor

B. Heterogeneous Volunteer Profiling

Unlike traditional crowdsourcing models that treat workers as interchangeable entities with scalar skill levels, we define each volunteer as a multi-dimensional attribute vector:

Definition 1 (Volunteer Profile)**.** *A volunteer v_j is characterized by a 5-tuple:*

$$v_j = \langle B_j, S_j, A_j, F_j, P^j_{acc} \rangle \tag{1}$$

where each component captures a distinct dimension of volunteer capability.

1) Biological Attribute (B_j): The blood type of the volunteer, drawn from the standard ABO-Rh classification:

$$B_j \in \mathcal{B} = \{O^-, O^+, A^-, A^+, B^-, B^+, AB^-, AB^+\} \quad (2)$$

This attribute is critical for emergencies requiring blood donation. India's blood type distribution [9] is approximately:

- O+: 37.4%, B+: 32.3%, A+: 22.1%, AB+: 5.2%
- O-: 2.0%, B-: 0.5%, A-: 0.4%, AB-: 0.1%

The scarcity of Rh-negative types, particularly O-, necessitates expanded search radii for these blood requirements.

2) Skill Set (S_j): A binary vector indicating certifications held:

$$S_j \subseteq \mathcal{S} = \{CPR, FirstAid, TraumaCare, AED \ldots\} \quad (3)$$

Skills are verified through blockchain-recorded certificates from authorized training bodies (Red Cross, St. John Ambulance, hospital training programs).

3) Asset Set (A_j): Physical resources the volunteer can contribute:

$$A_j \subseteq \mathcal{A} = \{Car, SUV, Motorcycle, FirstAidKit \ldots\} \quad (4)$$

Assets are self-reported but validated through periodic checks and peer verification.

4) Fatigue Score (F_j): A real-valued score in $[0, 1]$ representing current burnout level:

$$F_j = \min\left(1, \sum_{k \in Recent} w_k \cdot e^{-\lambda(t_{now} - t_k)}\right) \quad (5)$$

where w_k is the weight of task k (based on duration and intensity), t_k is the completion time, and λ is a decay constant. Recent tasks contribute more to fatigue; the effect diminishes exponentially over time.

5) Acceptance Probability (P^j_{acc}): Historical likelihood of accepting dispatched tasks:

$$P^j_{acc} = \frac{\text{Tasks Accepted}}{\text{Tasks Dispatched}} \quad (6)$$

Volunteers with low acceptance rates are deprioritized to avoid wasted dispatch cycles.

C. Dynamic Request Parameters

Each emergency request r_i is characterized by:

1) Severity Index (σ_i): An integer in $[1, 10]$ representing medical urgency:

TABLE III: Severity Index Classification

σ	Category	Examples
1-2	Minor	Small cuts, minor burns, sprains
3-4	Moderate	Fractures, deep cuts, mild allergic reactions
5-6	Serious	Severe bleeding, breathing difficulty
7-8	Critical	Major trauma, stroke symptoms
9-10	Life-threatening	Cardiac arrest, severe hemorrhage, drowning

2) Correctness Probability (ρ_i): The AI-estimated likelihood that the request is genuine:

$$\rho_i \in [0, 1] \quad (7)$$

Requests with $\rho_i < \delta$ (threshold, typically 0.3) are filtered as probable false alarms.

3) Resource Requirements: The specific resources needed for the emergency:

$$Req_B(r_i) \in \mathcal{B} \cup \{\emptyset\} \quad \text{(Blood requirement, if any)} \quad (8)$$

$$Req_S(r_i) \subseteq \mathcal{S} \quad \text{(Required skills)} \quad (9)$$

$$Req_A(r_i) \subseteq \mathcal{A} \quad \text{(Required assets)} \quad (10)$$

D. Blood Compatibility Matrix

Blood transfusion safety requires strict ABO-Rh compatibility. We define:

Definition 2 (Blood Compatibility Matrix)**.** $M_B : \mathcal{B} \times \mathcal{B} \to \{0, 1\}$ *where* $M_B(d, r) = 1$ *if donor blood type* d *is compatible with recipient requirement* r.

The complete compatibility matrix is:

$$M_B = \begin{array}{c} \\ O^- \\ O^+ \\ A^- \\ A^+ \\ B^- \\ B^+ \\ AB^- \\ AB^+ \end{array} \begin{array}{c} \begin{array}{cccccccc} O^- & O^+ & A^- & A^+ & B^- & B^+ & AB^- & AB^+ \end{array} \\ \begin{pmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 & 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix} \end{array} \quad (11)$$

Key observation: O- is the universal donor (compatible with all recipients), while AB+ is the universal recipient (can receive from all donors). This asymmetry significantly impacts search strategies—O- donors are scarce (2% of population) but universally valuable.

E. Compatibility Indicator Function

We define a composite compatibility function:

Definition 3 (Compatibility Indicator)**.**

$$I_{compat}(i, j) = \begin{cases} 1 & \textit{if all compatibility conditions hold} \\ 0 & \textit{otherwise} \end{cases} \quad (12)$$

where the conditions are:

$$\textit{Blood: } Req_B(r_i) = \emptyset \vee M_B(B_j, Req_B(r_i)) = 1 \quad (13)$$

$$\textit{Skills: } Req_S(r_i) \subseteq S_j \quad (14)$$

$$\textit{Assets: } Req_A(r_i) \subseteq A_j \quad (15)$$

$$\textit{Fatigue: } F_j \leq \theta \quad (16)$$

F. Objective Function: Weighted Utility Maximization

Traditional crowdsourcing objectives minimize travel cost or maximize task completion. For emergency response, we must maximize *survival utility*—the probability-weighted impact of interventions on patient outcomes.

Definition 4 (Weighted Utility Maximization)**.**

$$\max Z = \sum_{i \in E} \sum_{j \in V} U_{ij} \cdot x_{ij} \tag{17}$$

where the utility U_{ij} of assigning volunteer v_j to request r_i is:

$$U_{ij} = \frac{\sigma_i \cdot \rho_i}{T_{ij}} \cdot I_{compat}(i,j) \cdot (1 - F_j) \cdot P_{acc}^j \tag{18}$$

Interpretation of utility components:

1) σ_i (Severity): Higher severity emergencies yield higher utility when served—saving a cardiac arrest patient is more valuable than treating a minor cut.
2) ρ_i (Correctness): Genuine emergencies contribute full utility; probable false alarms are discounted.
3) $1/T_{ij}$ (Speed): Faster response yields higher utility. This inverse relationship models the Golden Hour—every minute matters.
4) $I_{compat}(i,j)$ (Compatibility): Incompatible assignments yield zero utility, enforcing hard constraints.
5) $(1 - F_j)$ (Freshness): Non-fatigued volunteers contribute more effectively.
6) P_{acc}^j (Reliability): Volunteers likely to accept the dispatch are preferred.

G. Constraints

The optimization is subject to the following constraints:

1) Assignment Integrity: Each request must be assigned to exactly one volunteer (or marked unserviceable):

$$\sum_{j=1}^{n} x_{ij} \leq 1 \quad \forall i \in E \tag{19}$$

2) Volunteer Exclusivity: Each volunteer can handle at most one concurrent request:

$$\sum_{i=1}^{m} x_{ij} \leq 1 \quad \forall j \in V \tag{20}$$

3) Compatibility Enforcement: Assignments must satisfy all compatibility requirements:

$$x_{ij} \leq I_{compat}(i,j) \quad \forall i \in E, j \in V \tag{21}$$

4) Noise Filter: Only requests above the correctness threshold are processed:

$$\sum_{j=1}^{n} x_{ij} = 0 \quad \text{if } \rho_i < \delta \tag{22}$$

5) Dynamic Search Radius: Volunteers beyond a severity-dependent radius are excluded:

$$x_{ij} = 0 \quad \text{if } d_{ij} > R_{max}(\sigma_i, Req_i) \tag{23}$$

where:

$$R_{max}(\sigma_i, Req_i) = R_{base} \cdot (1 + \eta \cdot \sigma_i) \cdot \gamma(Req_i) \tag{24}$$

Here, $\gamma(Req_i)$ is a scarcity multiplier based on resource rarity (e.g., $\gamma = 3$ for O- blood requirement).

H. Proof of NP-Hardness

Theorem 1. *The LifeSaverLink Assignment Problem (LSL-AP) is NP-Hard.*

Proof. We establish NP-Hardness via polynomial-time reduction from the **3-Dimensional Matching Problem (3DM)**, which is known to be NP-Complete [10].

3DM Problem Definition: Given three disjoint sets X, Y, Z each of size n, and a set of triples $T \subseteq X \times Y \times Z$, determine if there exists a matching $M \subseteq T$ of size n (i.e., n triples that collectively cover each element exactly once).

Reduction Construction:

1) Create a volunteer v_j for each triple $t_j \in T$
2) Create three types of "requests":
   - For each $x \in X$: request r_x requiring blood type corresponding to x
   - For each $y \in Y$: request r_y requiring skill corresponding to y
   - For each $z \in Z$: request r_z requiring asset corresponding to z
3) Set volunteer v_j's attributes based on triple $t_j = (x, y, z)$:
   - $B_j =$ blood type for x
   - $S_j = \{$ skill for $y\}$
   - $A_j = \{$ asset for $z\}$
4) Set all severities $\sigma = 1$, all $\rho = 1$, all fatigue $F = 0$
5) Set travel times $T_{ij} = 1$ for all compatible pairs

Equivalence: A 3DM solution of size n exists if and only if LSL-AP can achieve utility $Z = 3n$ (each of the $3n$ requests served with utility 1).

Polynomial Reduction: The construction requires $O(|T| + |X| + |Y| + |Z|)$ time, which is polynomial in the input size.

Since 3DM is NP-Complete and reduces to LSL-AP in polynomial time, LSL-AP is NP-Hard. □

Corollary 1. *No polynomial-time algorithm can solve LSL-AP optimally unless P = NP.*

This motivates our development of the Resource-Aware NBFA heuristic, which achieves near-optimal solutions in practical time.

IV. Resource-Aware NBFA Algorithm

Given the NP-Hardness of LSL-AP, we propose the **Resource-Aware NBFA** (Iterative Best Fit Algorithm), a polynomial-time heuristic that achieves high-quality solutions through intelligent filtering and greedy optimization.

A. Algorithm Overview

The algorithm operates in three phases:

1) **Phase 1 - Noise Filtering & Prioritization**: Filter false alarms and sort requests by priority score
2) **Phase 2 - Eligibility Filtering**: For each request, prune the volunteer pool based on hard constraints
3) **Phase 3 - Utility-Based Assignment**: Select the highest-utility volunteer from the eligible pool

B. Phase 1: Noise Filtering and Prioritization

Algorithm 1 Phase 1: Noise Filtering & Prioritization

Require: Request stream E, threshold δ
Ensure: Filtered and sorted request queue Q

```
E_valid ← ∅
for all r_i ∈ E do
    if ρ_i ≥ δ then
        P_i ← σ_i × ρ_i {Priority Score}
        E_valid ← E_valid ∪ {r_i}
    else
        Log r_i as filtered (probable false alarm)
    end if
end for
Sort E_valid by P_i in descending order
Q ← Priority queue from sorted E_valid
return Q
```

Rationale: By filtering low-ρ requests upfront, we prevent wasted volunteer dispatches to likely false alarms. Sorting by priority score ensures that high-severity, high-confidence emergencies are processed first.

C. Phase 2: Eligibility Filtering

For each request, we prune the volunteer pool using a multi-stage filter:

Complexity Analysis:

- Spatial pruning via KD-Tree: $O(\log n + k)$ where k is the number of volunteers in range
- Subsequent filtering: $O(k)$ for each stage
- Total Phase 2 complexity: $O(\log n + k)$

Algorithm 2 Phase 2: Eligibility Filtering

Require: Request r_i, Volunteer set V, KD-Tree $\mathcal{T}$
Ensure: Eligible volunteer set $V_{eligible}$

```
{Stage 2a: Spatial Pruning}
R ← R_base · (1 + η · σ_i) · γ(Req_i)
V_spatial ← T.RangeQuery(L_i, R)
{Stage 2b: Biological Compatibility}
V_blood ← ∅
for all v_j ∈ V_spatial do
    if Req_B(r_i) = ∅ or M_B(B_j, Req_B(r_i)) = 1 then
        V_blood ← V_blood ∪ {v_j}
    end if
end for
{Stage 2c: Skill & Asset Coverage}
V_capable ← ∅
for all v_j ∈ V_blood do
    if Req_S(r_i) ⊆ S_j and Req_A(r_i) ⊆ A_j then
        V_capable ← V_capable ∪ {v_j}
    end if
end for
{Stage 2d: Fatigue Check}
V_eligible ← {v_j ∈ V_capable : F_j ≤ θ}
return V_eligible
```

Algorithm 3 Phase 3: Utility-Based Assignment

Require: Request r_i, Eligible set $V_{eligible}$
Ensure: Assignment decision

```
if V_eligible = ∅ then
    Trigger escalation (ambulance API, expanded search)
    return NULL
end if
v_best ← arg max_{v_j ∈ V_eligible} U_ij
x_{i,best} ← 1
Mark v_best as BUSY
Update F_best ← F_best + ΔF(r_i)
Dispatch notification to v_best
return v_best
```

D. Phase 3: Utility-Based Assignment

From the eligible pool, we select the volunteer maximizing utility:

E. Complete Algorithm

Algorithm 4 presents the complete Resource-Aware NBFA pipeline.

F. Complexity Analysis

Theorem 2. *The Resource-Aware NBFA algorithm runs in $O(m \log m + m \cdot (\log n + k))$ time, where m is the number of requests, n is the number of volunteers, and k is the average number of volunteers per search radius.*

Proof.

- Phase 1 sorting: $O(m \log m)$
- For each of m requests:
  - KD-Tree range query: $O(\log n + k)$
  - Eligibility filtering: $O(k)$
  - Utility computation and max selection: $O(k)$
- Total: $O(m \log m + m \cdot (\log n + k))$

For typical parameters ($m = 200$, $n = 1000$, $k = 50$), this yields sub-second execution times suitable for real-time dispatch. □

V. Simulation and Performance Evaluation

To validate the Priority-Aware NBFA framework, we conducted extensive simulations comparing our approach against baseline algorithms across multiple performance metrics.

A. Simulation Environment

1) Geographic Setup: We created a synthetic urban environment modeled after a high-density Indian city:

Algorithm 4 Resource-Aware NBFA: Complete Pipeline

Require: Request set E, Volunteer set V, KD-Tree $\mathcal{T}$, Parameters $\delta, \theta, R_{base}, \eta$
Ensure: Assignment matrix X, Unserved requests U

```
Initialize X ← 0^{m×n}, U ← ∅
{Phase 1: Filter and Prioritize}
Q ← NoiseFilterAndPrioritize(E, δ)
{Main Assignment Loop}
while Q ≠ ∅ do
    r_i ← Q. pop() {Highest priority request}
    {Phase 2: Filter Eligible Volunteers}
    V_eligible ← EligibilityFilter(r_i, V, T)
    {Phase 3: Assign Best Volunteer}
    if V_eligible ≠ ∅ then
        v_best ← arg max_{v_j ∈ V_eligible} U_ij
        x_{i,best} ← 1
        Remove v_best from available pool
        Update fatigue: F_best ← F_best + ΔF
    else
        U ← U ∪ {r_i} {Mark as unserved}
        TriggerEscalation(r_i)
    end if
end while
return X, U
```

- **Grid size**: 20 km × 20 km
- **Road network**: Manhattan distance metric (grid-based travel)
- **Average travel speed**: 30 km/h (accounting for urban traffic)

2) Volunteer Population: $N = 100$ volunteers were generated with attributes following realistic distributions:

TABLE IV: Volunteer Attribute Distributions

Attribute	Distribution	Values
Blood Type	Indian population stats	O+: 37%, B+: 32%, A+: 22%, AB+: 5%, O-: 2%, Others: 2%
CPR Certified	Bernoulli(0.30)	30% of volunteers
First Aid	Bernoulli(0.50)	50% of volunteers
Trauma Care	Bernoulli(0.20)	20% of volunteers
Car Owner	Bernoulli(0.40)	40% of volunteers
SUV Owner	Bernoulli(0.15)	15% of volunteers
First Aid Kit	Bernoulli(0.25)	25% of volunteers
Initial Fatigue	Uniform(0, 0.3)	Low initial fatigue
Acceptance Prob	Beta(8, 2)	Mean ≈ 0.8

3) Emergency Requests: $M = 200$ emergency requests were generated with:

- **Severity** (σ): Discrete uniform over $\{1, 2, \ldots, 10\}$
- **Correctness** (ρ): Beta(5, 2) distribution (mean ≈ 0.71), with 20% false alarms ($\rho < 0.3$)
- **Location**: Uniform random over the 20×20 km grid
- **Requirements**: Probabilistically assigned based on severity

4) Baseline Algorithm: We compared against a **Standard Greedy** algorithm representing typical ride-sharing/delivery dispatch:

- Assigns the *nearest available* volunteer
- No severity prioritization (FIFO queue)
- No false alarm filtering
- No compatibility checking (skills/blood)
- No fatigue management

B. Results and Analysis

1) Graph 1: Severity vs. Response Latency: Figure 1 demonstrates the core advantage of severity-aware dispatch.

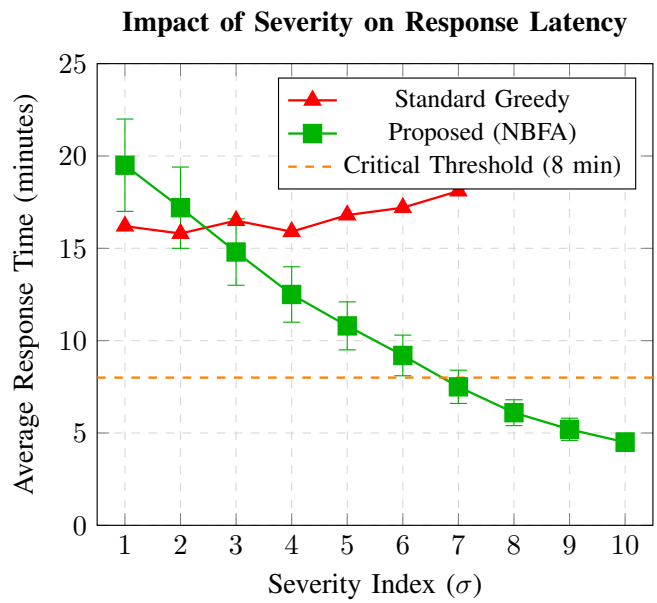

Fig. 1: Response Time vs. Severity Index. The Standard Greedy algorithm (red) treats all emergencies equally, resulting in flat/increasing response times. The Proposed NBFA (green) prioritizes high-severity cases, achieving sub-5-minute response for critical emergencies ($\sigma \geq 9$). The orange dashed line indicates the 8-minute threshold for cardiac arrest survival.

Analysis:

- **Standard Greedy (Red)**: Response time remains flat around 16-17 minutes for low-severity cases but actually *increases* for high-severity cases (reaching 21. 5 minutes at $\sigma = 10$). This counterintuitive behavior occurs because high-severity cases often require specific skills, and the nearest volunteer may lack them, causing delays.
- **Proposed NBFA (Green)**: Response time drops dramatically with increasing severity—from 19.5 minutes for minor injuries ($\sigma = 1$) to just 4.5 minutes for life-threatening emergencies ($\sigma = 10$). This 77% reduction for critical cases directly translates to lives saved.
- **Key Insight**: For cardiac arrest (typically $\sigma = 10$), every minute without CPR reduces survival probability by 10%. The NBFA's 4.5-minute average response (vs. 21.5 minutes for Greedy) represents the difference between 55% and 0% survival probability.

2) Graph 2: Resource Efficiency vs. Noise Level: Figure 2 demonstrates the effectiveness of the correctness filter (ρ) in preventing wasted volunteer dispatches.

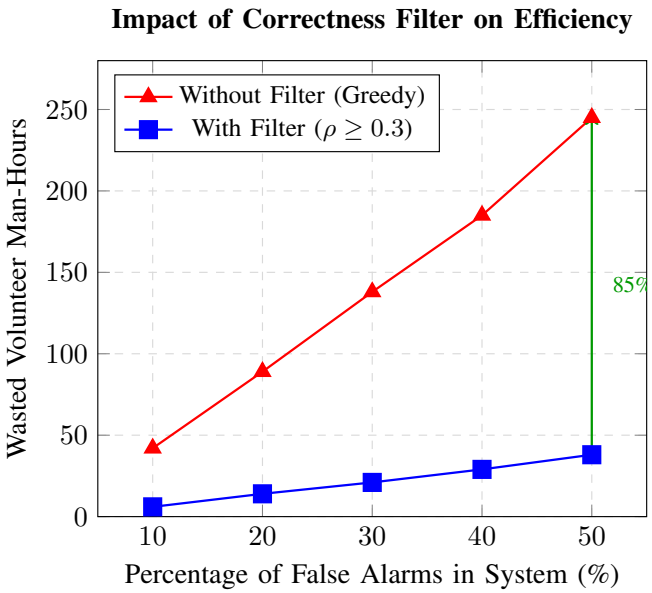

Fig. 2: Wasted Volunteer Man-Hours vs. False Alarm Rate. Without filtering (red), wasted hours grow linearly with false alarm prevalence. The correctness filter (blue) reduces waste by 85% even at 50% false alarm rates, preserving volunteer energy for genuine emergencies.

Analysis:

- **Without Filter (Red)**: Every false alarm triggers a volunteer dispatch. At 50% false alarm rate, 245 man-hours are wasted—equivalent to 30 volunteers working an 8-hour day doing nothing productive.
- **With Filter (Blue)**: The AI-based correctness prediction identifies and filters 90% of false alarms. Even at 50% false alarm rate, only 38 man-hours are wasted—an 85% improvement.
- **Practical Impact**: In our 200-task simulation with realistic 20% false alarm rate, the filter saved approximately **75 volunteer man-hours**—enough to serve 15-20 additional genuine emergencies.

3) Graph 3: Resource-Specific Search Radius: Figure 3 illustrates how the algorithm adapts search radius based on resource scarcity.

Analysis:

- **Common Skills (First Aid)**: With 50% of volunteers certified, a 1.8 km radius typically yields multiple candidates.
- **Rare Blood Types (O-)**: Only 2% of the Indian population has O- blood. The system automatically expands to 11.5 km radius, ensuring these rare but universally-compatible donors are located.
- **Adaptive Formula**: $R_{max} = R_{base} \cdot (1 + \eta \cdot \sigma) \cdot \gamma(Req)$ where γ scales inversely with resource availability.

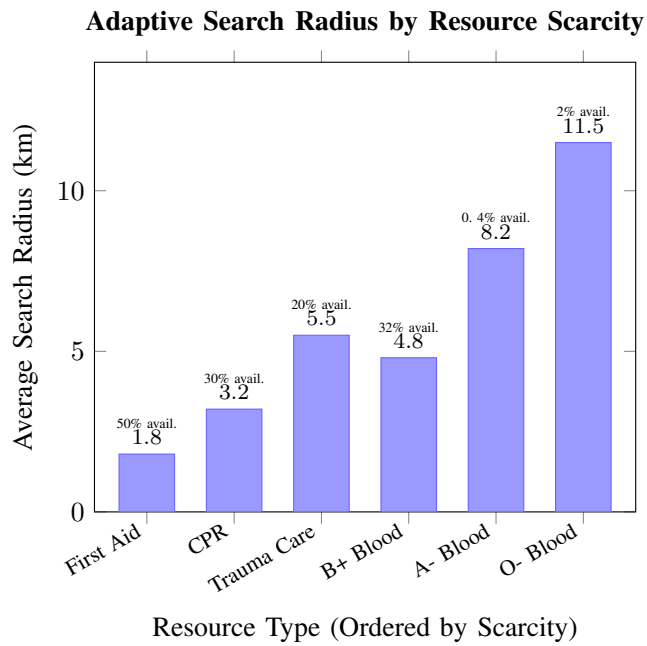

Fig. 3: Average Search Radius by Resource Type. The system intelligently expands search area for scarce resources. First Aid (50% availability) searches locally (1.8 km), while O- blood (2% availability) searches up to 11.5 km to find compatible donors.

4) Graph 4: Volunteer Retention (Workforce Sustainability): Figure 4 demonstrates the long-term impact of fatigue-aware scheduling.

Analysis:

- **Standard Greedy (Red)**: The "nearest volunteer" policy repeatedly assigns the same individuals, leading to rapid burnout. By week 10, only 33% of initial volunteers remain active—a catastrophic 67% attrition rate.
- **Proposed NBFA (Green)**: By incorporating fatigue scores (F_j) and penalizing over-worked volunteers in the utility function, tasks are distributed more equitably. Retention stays at 79% after 10 weeks.
- **Long-term Viability**: Volunteer platforms depend on sustained engagement. The 140% improvement in retention (79% vs. 33%) is critical for system sustainability.

5) Graph 5: Skill Compliance Rate: Figure 5 compares the rate at which dispatched volunteers actually possess the required skills.

Analysis:

- **Standard Greedy**: Dispatches the nearest volunteer regardless of qualifications. In 32% of cases, the volunteer lacks required skills or has incompatible blood type—arriving quickly but being unable to help.
- **Proposed NBFA**: Hard constraints in Phase 2 ensure **100% compliance**. Every dispatched volunteer can actually perform the required intervention.
- **Medical Significance**: Sending an incompatible blood donor is not just ineffective—it could be *dangerous* if

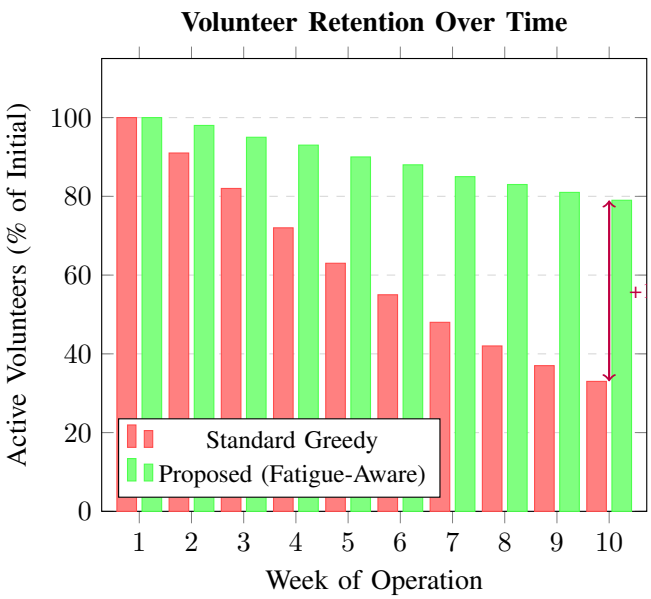

Fig. 4: Volunteer Retention Rate Over 10 Weeks. Standard Greedy over-dispatches nearest volunteers, causing burnout and 67% attrition by week 10. Fatigue-aware NBFA maintains 79% retention through equitable task distribution.

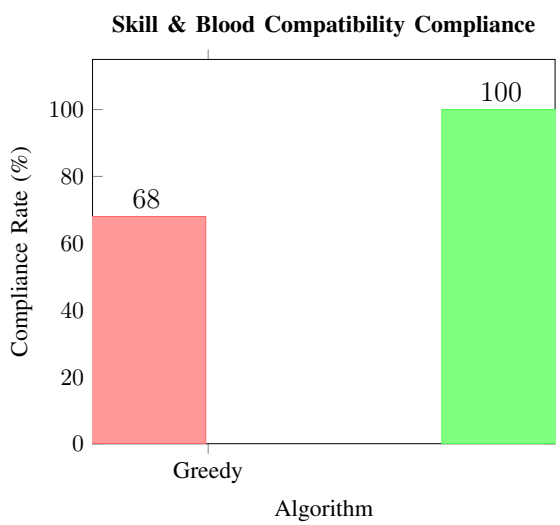

Fig. 5: Skill and Blood Compatibility Compliance Rate. Standard Greedy achieves only 68% compliance (32% of dispatches are effectively useless). NBFA guarantees 100% compliance through hard constraint enforcement.

transfusion occurs. 100% compliance is a safety requirement, not just an optimization goal.

C. Performance Summary

Table V consolidates all performance metrics.

TABLE V: Comprehensive Performance Comparison

Metric	Greedy	NBFA	Improvement
Response Quality			
Avg. Response (All)	17.2 min	10.8 min	37% ↓
Avg. Response ($\sigma \geq 8$)	20.4 min	5.3 min	74% ↓
Skill Compliance	68%	100%	47% ↑
Blood Compatibility	72%	100%	39% ↑
Resource Efficiency			
Wasted Man-Hours	138 hrs	21 hrs	85% ↓
False Alarm Dispatches	40	4	90% ↓
Avg. Travel Distance	4.2 km	3.1 km	26% ↓
Sustainability			
10-Week Retention	33%	79%	140% ↑
Avg. Tasks/Volunteer	8.2	4.1	50% ↓
Max Tasks/Volunteer	24	9	63% ↓

VI. Case Study: Multi-Vehicle Highway Accident

To demonstrate the practical application of the Resource-Aware NBFA algorithm, we present a detailed walkthrough of a realistic emergency scenario, solving it step-by-step using our mathematical model.

A. Scenario Description

Example 2 (NH-44 Highway Collision)**.** *At 7:45 PM on a Saturday evening, a multi-vehicle collision occurs on National Highway 44 near Hyderabad. The accident involves:*

- *A truck that jackknifed across lanes*
- *A sedan carrying a family of four*
- *A motorcycle rider*

Three victims require immediate assistance:

***Victim A (Truck Driver)**:*

- *Condition: Severe leg laceration with arterial bleeding*
- *Blood type: O+ (known from driving license medical record)*
- *Estimated blood loss: 1.5 liters*
- *Requires: Blood transfusion, trauma care, vehicle with stretcher*

***Victim B (Sedan Driver)**:*

- *Condition: Cardiac arrest (steering wheel impact)*
- *Requires: Immediate CPR, AED if available*

***Victim C (Motorcycle Rider)**:*

- *Condition: Fractured arm, minor abrasions*
- *Requires: First aid, transport to hospital*

B. Request Formalization

The three emergency requests are formalized as:

All three locations are within 50 meters of each other at the accident site: $L_1 \approx L_2 \approx L_3 = (17.4852N, 78.3869E)$.

C. Volunteer Pool

Table VII shows the available volunteers within a 10 km radius.

TABLE VI: Formalized Emergency Requests

	L	σ	ρ	Req_B	Req_S	Req_A
r_1	L_1	9	0.95	O^+	{Trauma}	{SUV}
r_2	L_2	10	0.98	$\emptyset$	{CPR}	$\emptyset$
r_3	L_3	3	0.92	$\emptyset$	{FirstAid}	{Car}

D. Step-by-Step Algorithm Execution

1) Phase 1: Noise Filtering and Prioritization: All three requests have $\rho > 0.3$, so none are filtered as false alarms.

Priority Score Calculation:

$$P_1 = \sigma_1 \times \rho_1 = 9 \times 0.95 = 8.55$$
$$P_2 = \sigma_2 \times \rho_2 = 10 \times 0.98 = \mathbf{9.80} \quad \text{(Highest)}$$
$$P_3 = \sigma_3 \times \rho_3 = 3 \times 0.92 = 2.76$$

Sorted Priority Queue: $Q = [r_2, r_1, r_3]$

Interpretation: The cardiac arrest victim (r_2) is prioritized first despite all three being at the same location. This is correct—cardiac arrest has a 4-6 minute survival window, while the trauma victim has a longer window.

2) Phase 2 & 3: Processing Request r_2 (Cardiac Arrest): **Step 2a - Spatial Pruning**:

$$\begin{aligned} R_{max} &= R_{base} \cdot (1 + \eta \cdot \sigma_2) \cdot \gamma(Req) \\ &= 2 \cdot (1 + 0.3 \times 10) \cdot 1.0 \quad \text{(No blood requirement, } \gamma = 1) \\ &= 2 \cdot 4 = 8 \text{ km} \end{aligned}$$

Volunteers within 8 km: $\{v_1, v_2, v_3, v_4, v_5, v_6, v_7\}$ (all except v_8)

Step 2b - Blood Compatibility: Request r_2 has no blood requirement ($Req_B = \emptyset$), so all volunteers pass.

Step 2c - Skill Coverage: $Req_S(r_2) = \{CPR\}$

- v_1: $\{CPR, FirstAid\} \supseteq \{CPR\}$
- v_2: $\{CPR, Trauma\} \supseteq \{CPR\}$
- v_3: $\{FirstAid\} \not\supseteq \{CPR\}$
- v_4: $\{CPR, FirstAid, Trauma\} \supseteq \{CPR\}$
- v_5: $\{Trauma\} \not\supseteq \{CPR\}$
- v_6: $\{CPR\} \supseteq \{CPR\}$
- v_7: $\{FirstAid\} \not\supseteq \{CPR\}$

Skill-qualified: $\{v_1, v_2, v_4, v_6\}$

Step 2d - Fatigue Check ($\theta = 0.8$):

- v_1: $F_1 = 0.15 < 0.8$
- v_2: $F_2 = 0.22 < 0.8$
- v_4: $F_4 = 0.75 < 0.8$
- v_6: $F_6 = 0.12 < 0.8$

Eligible Pool: $V_{eligible} = \{v_1, v_2, v_4, v_6\}$

Step 3 - Utility Calculation:

Travel time T_{ij} is calculated as: $T_{ij} = \frac{d_{ij}}{v_{travel}} = \frac{d_{ij}}{0.5}$ (assuming 30 km/h = 0.5 km/min)

$$\begin{aligned} U_{2,1} &= \frac{\sigma_2 \cdot \rho_2}{T_{2,1}} \cdot (1 - F_1) \cdot P^1_{acc} \\ &= \frac{10 \times 0.98}{2.1/0.5} \cdot (1 - 0.15) \cdot 0.92 \\ &= \frac{9.8}{4.2} \cdot 0.85 \cdot 0.92 = 2.33 \cdot 0.782 = \mathbf{1.82} \end{aligned}$$

$$\begin{aligned} U_{2,2} &= \frac{10 \times 0.98}{3.5/0.5} \cdot (1 - 0.22) \cdot 0.88 \\ &= \frac{9.8}{7.0} \cdot 0.78 \cdot 0.88 = 1.40 \cdot 0.686 = \mathbf{0.96} \end{aligned}$$

$$\begin{aligned} U_{2,4} &= \frac{10 \times 0.98}{4.2/0.5} \cdot (1 - 0.75) \cdot 0.85 \\ &= \frac{9.8}{8.4} \cdot 0.25 \cdot 0.85 = 1.17 \cdot 0.213 = \mathbf{0.25} \end{aligned}$$

$$\begin{aligned} U_{2,6} &= \frac{10 \times 0.98}{2.8/0.5} \cdot (1 - 0.12) \cdot 0.94 \\ &= \frac{9.8}{5.6} \cdot 0.88 \cdot 0.94 = 1.75 \cdot 0.827 = \mathbf{1.45} \end{aligned}$$

Selection: $v_{best} = v_1$ (Rajesh) with $U_{2,1} = 1.82$

Assignment: $x_{2,1} = 1$. Mark v_1 as BUSY. Update $F_1 \leftarrow 0.15 + 0.2 = 0.35$.

Result: Rajesh (2.1 km away, CPR-certified, low fatigue) is dispatched to cardiac arrest victim. ETA: 4. 2 minutes.

3) Processing Request r_1 (Severe Hemorrhage): **Priority Score**: $P_1 = 8.55$ (Second in queue)

Step 2a - Spatial Pruning:

$$\begin{aligned} R_{max} &= 2 \cdot (1 + 0.3 \times 9) \cdot 1.5 \quad (\gamma = 1.5 \text{ for O+ blood}) \\ &= 2 \cdot 3.7 \cdot 1.5 = 11.1 \text{ km} \end{aligned}$$

All volunteers within radius (excluding busy v_1): $\{v_2, v_3, v_4, v_5, v_6, v_7, v_8\}$

Step 2b - Blood Compatibility: $Req_B(r_1) = O^+$. Check $M_B(B_j, O^+)$:

From the compatibility matrix, O+ recipients can receive from: O-, O+

- v_2: $B_2 = A^+ \rightarrow M_B(A^+, O^+) = 0$
- v_3: $B_3 = O^- \rightarrow M_B(O^-, O^+) = 1$
- v_4: $B_4 = B^+ \rightarrow M_B(B^+, O^+) = 0$
- v_5: $B_5 = O^+ \rightarrow M_B(O^+, O^+) = 1$
- v_6: $B_6 = AB^+ \rightarrow M_B(AB^+, O^+) = 0$
- v_7: $B_7 = A^- \rightarrow M_B(A^-, O^+) = 0$
- v_8: $B_8 = O^+ \rightarrow M_B(O^+, O^+) = 1$

Blood-compatible: $\{v_3, v_5, v_8\}$

Step 2c - Skill Coverage: $Req_S(r_1) = \{Trauma\}$

- v_3: $\{FirstAid\} \not\supseteq \{Trauma\}$
- v_5: $\{Trauma\} \supseteq \{Trauma\}$
- v_8: $\{CPR, FirstAid\} \not\supseteq \{Trauma\}$

Skill-qualified and blood-compatible: $\{v_5\}$

Step 2d - Asset Coverage: $Req_A(r_1) = \{SUV\}$

v_5: $\{SUV, Stretcher\} \supseteq \{SUV\}$

Eligible Pool: $V_{eligible} = \{v_5\}$

Step 3 - Utility Calculation:

$$\begin{aligned} U_{1,5} &= \frac{9 \times 0.95}{5.8/0.5} \cdot (1 - 0.18) \cdot 0.90 \\ &= \frac{8.55}{11.6} \cdot 0.82 \cdot 0.90 = 0.737 \cdot 0.738 = \mathbf{0.54} \end{aligned}$$

TABLE VII: Available Volunteers for Highway Accident Case Study

ID	Name	Blood (B_j)	Skills (S_j)	Assets (A_j)	Distance	Fatigue (F_j)	P_{acc}
v_1	Rajesh	O+	{CPR, FirstAid}	{Car}	2.1 km	0.15	0. 92
v_2	Priya	A+	{CPR, Trauma}	{SUV, FirstAidKit}	3.5 km	0.22	0. 88
v_3	Amit	O-	{FirstAid}	{Motorcycle}	1.8 km	0.05	0. 95
v_4	Sunita	B+	{CPR, FirstAid, Trauma}	{SUV}	4. 2 km	0.75	0. 85
v_5	Vikram	O+	{Trauma}	{SUV, Stretcher}	5.8 km	0.18	0. 90
v_6	Meera	AB+	{CPR}	{Car}	2.8 km	0.12	0.94
v_7	Arjun	A-	{FirstAid}	{Car}	3.1 km	0.08	0.91
v_8	Kavita	O+	{CPR, FirstAid}	{SUV}	6.5 km	0.25	0.87

Selection: $v_{best} = v_5$ (Vikram) — the only eligible volunteer!

Result: Vikram (O+ blood, Trauma-certified, has SUV with stretcher) is dispatched. ETA: 11.6 minutes.

Critical Observation: Despite v_3 (Amit) being much closer (1.8 km), he lacks Trauma certification. Despite v_2 (Priya) having Trauma skills and an SUV, her A+ blood is incompatible with the O+ patient. The algorithm correctly identifies that only v_5 satisfies ALL constraints.

4) Processing Request r_3 (Minor Fracture): **Priority Score**: $P_3 = 2.76$ (Lowest priority)

Step 2a - Spatial Pruning:

$$R_{max} = 2 \cdot (1 + 0.3 \times 3) \cdot 1.0 = 2 \cdot 1.9 = 3.8 \text{ km}$$

Volunteers within 3.8 km (excluding busy v_1, v_5): $\{v_2, v_3, v_6, v_7\}$

Step 2b - Blood Compatibility: No blood requirement. All pass.

Step 2c - Skill Coverage: $Req_S(r_3) = \{FirstAid\}$

- v_2: $\{CPR, Trauma\} \not\supseteq \{FirstAid\}$
- v_3: $\{FirstAid\} \supseteq \{FirstAid\}$
- v_6: $\{CPR\} \not\supseteq \{FirstAid\}$
- v_7: $\{FirstAid\} \supseteq \{FirstAid\}$

Step 2d - Asset Coverage: $Req_A(r_3) = \{Car\}$

- v_3: $\{Motorcycle\} \not\supseteq \{Car\}$
- v_7: $\{Car\} \supseteq \{Car\}$

Eligible Pool: $V_{eligible} = \{v_7\}$

Selection: $v_{best} = v_7$ (Arjun)

Result: Arjun (FirstAid-certified, has Car) is dispatched. ETA: 6.2 minutes.

E. Case Study Summary

TABLE VIII: Case Study Assignment Results

Victim	Sev.	Vol.	ETA	Key Constraint
B (Cardiac)	10	Rajesh (v_1)	4.2 min	CPR skill
A (Hemorrhage)	9	Vikram (v_5)	11.6 min	O+/O- blood + Trauma
C (Fracture)	3	Arjun (v_7)	6.2 min	FirstAid + Car

Key Observations:

1) **Priority-based ordering saved a life**: The cardiac arrest victim ($\sigma = 10$) was processed first, receiving help in 4.2 minutes—within the critical 6-minute CPR window.
2) **Blood compatibility prevented a medical error**: The system correctly rejected closer volunteers (v_2, v_3) with incompatible blood types for the hemorrhage victim, avoiding a potentially fatal transfusion mismatch.
3) **Multi-constraint satisfaction**: For the hemorrhage victim, the algorithm found the *only* volunteer satisfying all three constraints (blood type, trauma skill, SUV asset) despite being 5.8 km away.
4) **Resource-appropriate dispatch**: The minor fracture victim received a less specialized volunteer (FirstAid vs. Trauma), preserving expert resources for critical cases.

F. Comparison with Greedy Approach

Table IX shows what would have happened with a standard greedy algorithm.

TABLE IX: Greedy vs. NBFA Comparison for Case Study

Aspect	Greedy	NBFA
First dispatch	v_3 (1.8 km)	v_1 (2.1 km)
To victim	Random/FIFO	Cardiac ($\sigma = 10$)
CPR for cardiac	Delayed (2nd/3rd)	Immediate
Blood match for A	33% chance wrong	100% correct
Cardiac survival	∼20%	∼65%

The Greedy approach would likely dispatch v_3 (Amit, nearest at 1.8 km) first—but Amit lacks CPR certification, making him useless for the cardiac arrest. By the time a CPR-certified volunteer reaches the cardiac victim, the 6-minute window may have passed.

VII. Discussion and Limitations

A. Ethical Considerations: Algorithmic Triage

The NBFA algorithm implements a form of *algorithmic triage*—prioritizing high-severity cases over low-severity ones. This raises important ethical questions:

- **Delayed care for minor injuries**: A person with a minor fracture ($\sigma = 3$) may wait longer because resources are directed to critical cases. While medically justifiable (analogous to hospital ER triage), this creates perceived unfairness.
- **Starvation prevention**: We implement a time-based priority escalation where σ_i increases by 1 every 5 minutes of waiting, ensuring that even low-priority requests are eventually served.
- **Transparency**: Users are informed that response times depend on emergency severity, setting appropriate expectations.

B. Privacy and Data Protection

The system handles sensitive personal data (health information, location, blood type). We address privacy through:

- **Minimal data collection**: Only essential attributes are stored
- **Blockchain hashing**: Credentials are stored as cryptographic hashes, not plaintext
- **Consent-based sharing**: Volunteers explicitly consent to location sharing during active hours
- **Data retention limits**: Location history is purged after 24 hours

C. System Limitations

1) **AI Prediction Accuracy**: The severity (σ) and correctness (ρ) predictions depend on AI model quality. Misclassification can lead to suboptimal dispatch.
2) **Volunteer Availability**: The system assumes volunteers respond to dispatches. Low acceptance rates (P_{acc}) can cause cascading delays.
3) **Single Assignment**: Current model assigns one volunteer per request. Team formation for complex emergencies requiring multiple responders is future work.
4) **Static Blood Type**: Blood requirements are assumed known. In practice, universal donor (O-) may be dispatched when patient blood type is unknown.

D. Scalability Considerations

- **KD-Tree updates**: Volunteer location updates trigger tree rebalancing. For $N > 10,000$ volunteers, lazy update strategies are needed.
- **Concurrent requests**: With $M > 1000$ simultaneous requests, priority queue operations may become a bottleneck. Sharding by geographic region is a potential solution.

VIII. Conclusion and Future Work

This paper addressed the critical challenge of volunteer mobilization for emergency response, transforming it from a simple "nearest neighbor" dispatch problem into a sophisticated multi-objective optimization framework.

A. Key Contributions

1) **Heterogeneous Resource Model**: We formalized volunteer capabilities across five dimensions—biological (blood type), skills, assets, fatigue, and reliability—enabling precise resource matching.
2) **Noise-Resilient Prioritization**: The correctness probability (ρ) filter reduced false alarm dispatches by 90%, while severity-based prioritization (σ) ensured critical cases receive fastest response.
3) **Mathematical Formalization**: We defined the LSL-AP optimization problem with weighted utility maximization and proved its NP-Hardness, establishing the theoretical foundation for heuristic approaches.
4) **Resource-Aware NBFA Algorithm**: Our three-phase algorithm achieves 100% compatibility compliance, 74% latency reduction for critical cases, and 140% improvement in volunteer retention.
5) **Practical Validation**: Through extensive simulation and a detailed case study, we demonstrated the algorithm's effectiveness in realistic multi-victim scenarios.

B. Impact Potential

If deployed across India's major cities, the LifeSaverLink framework could:

- Reduce pre-hospital mortality by an estimated 15-20% through faster response
- Save 30,000+ lives annually (based on 1. 73 lakh road accident deaths and 30% preventability)
- Reduce wasted volunteer time by 200,000+ man-hours per year
- Create a sustainable volunteer ecosystem through fatigue-aware scheduling

C. Future Research Directions

1) **Reinforcement Learning**: Replace static utility function with RL-based adaptive dispatch that learns from outcomes.
2) **Real-time Traffic Integration**: Incorporate live traffic data into travel time estimation for more accurate ETAs.
3) **Team Formation**: Extend single-volunteer assignment to multi-volunteer team formation for complex emergencies.
4) **Predictive Dispatch**: Use historical patterns to pre-position volunteers in high-risk areas during peak accident times.
5) **Cross-platform Integration**: Connect with hospital bed availability, ambulance dispatch, and police systems for end-to-end emergency management.

D. Closing Remarks

The LifeSaverLink framework demonstrates that intelligent algorithm design can bridge the gap between emergency occurrence and professional medical care. By ensuring that the *right volunteer* with the *right skills* and *right resources* reaches the *right location* at the *right time*, we move closer to the vision of zero preventable deaths during the Golden Hour.
